Overview

What This Report Contains

This is the principal report of the Alberta Energy and Utilities Board (EUB) on Alberta's reserves of conventional crude oil, oil sands, gas, ethane, natural gas liquids (NGL), and sulphur. It includes estimates of initial and remaining established reserves and ultimate potential. For the first time, this year's report has been separated into two documents. Volume 1 includes reserves of crude oil, oil sands, and gas, and Volume 2, to be released in June 2000, includes reserves of ethane, NGL, and sulphur.

Reserve Highlights 1999

Reserves	1999	Change from 1998
Conventional crude oil		
Initial established (10^6 m^3)	2 522	+32
Remaining established (10^6 m^3)	302	-14
Crude bitumen (surface-mineable)		
Initial established (10^6 m^3)	5 590	-1 140
Remaining established (10^6 m^3)	5 241	-1 164
Crude bitumen (in situ)		
Initial established (10^6 m^3)	22 740	+22 170
Remaining established (10^6 m^3)	22 607	+22 157
Natural gas		
Initial established (10^9 m^3)	3 919	+110
Remaining established (10^9 m^3)	1 207	-33
Production		
Conventional crude oil (10^6 m^3)	45	-5
Crude bitumen (surface-mineable) (10^6 m^3)	23	+3
Crude bitumen (in situ) (10^6 m^3)	12	-5
Natural gas (10^9 m^3)	142	+5

The reserves report is updated annually from EUB records. This edition reflects changes that have occurred to the end of 1999.

In addition to the detailed account of reserves, Volume 1 includes the Map of Designated Oil and Gas Fields, Oil Sands Deposits, Main Pipelines, Refineries, and Gas Processing Plants. The Terminology section provides a list of metric units and the imperial equivalents used in tables throughout the report, a glossary of specialized terminology, and lists of symbols and abbreviations used.

EUB-NEB Joint Database

The databases used to prepare this report are developed by the staff of the EUB. Input is also obtained from the National Energy Board (NEB) through an ongoing process of oil and gas reserve studies. This is the fifth EUB *Alberta's Reserves* report in which crude oil reserves data and gas reserves data tables present the official reserve estimates of both the EUB and the NEB for the province of Alberta, following the signing of the Common Reserves Data Base Agreement between the two organizations in 1994.

Available in Other Formats

The detailed pool-by-pool information on oil and gas reserves is available on diskette, CD ROM, magnetic tape, and cartridge tape. The gas information also includes those smaller gas pools ($300 \times 10^6 \text{ m}^3$) not listed in this report. Gas reserve details are also available on COM-microfiche (EUB *Statistical Series* 99-35). To obtain copies of any of these materials, contact EUB Information Services, 640 - 5 Avenue SW, Calgary AB T2P 3G4 (telephone: 403-297-8190; fax: 403-297-7040).

For More Information

Direct general inquiries regarding this report to Andy Burrowes (see below). Direct inquiries regarding specific sections as follows:

Crude oil	Andy Burrowes	(403) 297-8566
Oil sands	Keith Sadler	(403) 297-2886
Gas	Nehru Ramdin	(403) 297-3580

1 Reserves of Conventional Crude Oil

1.1 Provincial Summary

The EUB estimates the remaining established reserves of conventional crude oil in Alberta to be 302 million cubic metres (10^6 m^3) or 1.9 billion barrels at year-end 1999. This decrease from year-end 1998 of 14 million cubic metres is a result of all reserve adjustments less production that occurred during 1999. The changes in reserves and cumulative production for light-medium and heavy crude oil to year-end 1999 are shown in Table 1.1. Figure 1.1 depicts the trend in remaining reserves from 1976 to the present.

Table 1.1. Reserve change highlights (10^6 m^3)

	1999	1998	Change
Initial established reserves ^a			
Light-medium	2 209.9	2 191.6	+18.3
Heavy	<u>311.7</u>	<u>298.6</u>	<u>+13.1</u>
Total	2 521.6	2 490.1 (15 670) ^b	+31.5
Cumulative production ^a			
Light-medium	1 976.0	1 944.7	31.3 ^c
Heavy	<u>244.0</u>	<u>230.2</u>	<u>13.8 ^c</u>
Total	2 219.9	2 174.9	45.1 (284) ^b
Remaining established reserves ^a			
Light-medium	233.9	246.9	-13.0
Heavy	<u>67.8</u>	<u>68.4</u>	<u>- 0.6</u>
Total	301.6 (1 898) ^b	315.2 (1 984) ^b	-13.6

^aDiscrepancies are due to rounding.

^bImperial equivalent in millions of stock-tank barrels.

^cDiscrepancies may exist with actual production as reported in *Statistical Series 1999-17*.

The initial established reserves attributed to the 270 new oil pools booked in 1999 totalled 5.6 million cubic metres (the lowest since 1977), while development of new and existing pools during 1999 added another 7.2 million cubic metres. New and expanded enhanced recovery schemes added initial established reserves of 2.1 million cubic metres. Total net reassessment of existing reserves added 16.7 million cubic metres.

The resulting total increase in initial established reserves of 31.5 million cubic metres represents 69 per cent of Alberta's 1999 conventional crude oil production of 45.5 million cubic metres.

Reserve additions excluding reassessment totalled 14.9 million cubic metres, replacing 33 per cent of Alberta's 1999 production. A breakdown of the year's reserves changes is summarized in Table 1.2. A detailed history of reserve changes, including a breakdown by additions, reassessments, and enhanced recovery mechanisms, is shown in Figures 1.2 to 1.6. Annual production of Alberta's conventional crude oil since 1975 is shown in Figure 1.9.

Table 1.2. Breakdown of changes in initial established reserves (10⁶ m³)

	Light-medium	Heavy crude	Total
New discoveries	5.2	0.5	5.6
Development of existing pools	5.0	2.1	7.2
Enhanced recovery (new schemes/expansions)	1.5	0.6	2.1
Reassessment	<u>6.7</u>	<u>10.0</u>	<u>16.7</u>
Total	18.3	13.1	31.5

At year-end 1999, oil reserves were assigned to some 6800 light-medium and 2300 heavy crude oil pools in the province. Sixty-one per cent of these pools consist of a single well. The distribution of reserves by pool size is shown in Table 1.3, and Figure 1.7 shows oil pools discovered by size and year of discovery.

Table 1.3. Distribution of oil reserves by pool size

Pool size range ^a (10 ³ m ³)	Pools		Initial established reserves		Remaining established reserves	
	No.	%	10 ⁶ m ³	%	10 ⁶ m ³	%
1000 or more	276	3	2 090	83	194	64
100-999	1 023	11	315	12	75	25
30-99	1 308	14	72	3	19	6
1-29	<u>6 471</u>	<u>71</u>	<u>44</u>	<u>2</u>	<u>14</u>	<u>5</u>
Total	9 078	100	2 522	100	302	100

^aBased on initial established reserves.

Table 1.4 lists those pools having the largest reserve changes over the past year. The distribution of conventional crude oil reserves by drive mechanism, including their historical average recovery factors, is presented in Table 1.5 and Figure 1.8. Tables 1.6 and 1.7 and Figure 1.10 depict the distribution of reserves by geological period and by formation.

1.2 Ultimate Potential

The ultimate potential of conventional crude oil was estimated by the EUB in 1994 at 3130 million cubic metres, reflecting its estimate of geological prospects. Figure 1.11 shows Alberta's historical and forecast growth of initial established reserves. Figure 1.12 illustrates that approximately 71 per cent of the estimated ultimate potential for conventional crude oil has been produced to year-end 1999. Remaining established reserves of 302 million cubic metres account for 10 per cent of the ultimate potential. Initial established reserves therefore account for 81 per cent of the ultimate potential, leaving 19 per cent, or 608 million cubic metres, of conventional crude oil reserves yet to be discovered. This number added to the remaining established reserve yields 910 million cubic metres of conventional crude oil reserves that will be available for future production.

In 1999, both the remaining established reserves and the annual production of crude oil declined. The ratio of remaining reserve to production remained relatively steady at 6.7. The reserve-to-production ratio represents the remaining established reserves at year-end divided by the annual production (i.e., based on current production and no new drilling, the remaining established reserves would be produced in 6.7 years). However, as can be seen from Figure 1.12, there is an ultimate oil potential of 608 million cubic metres yet to be discovered, which will mitigate the impact of these declines. Therefore, this ratio cannot be considered to be the number of producing years remaining. Additions to existing pools and the discovery of new pools will continue to bring on new reserves and associated production each year, which will tend to keep the ratio relatively constant. The ratio within Alberta has been relatively constant since 1994, and this is expected to continue. A similar trend has been observed in basins within the United States, where the ratio has remained relatively constant for many years. Any future decline in conventional crude oil production within Alberta will be more than offset by increases in crude bitumen and synthetic production, as discussed in Section 2.

Table 1.4. Major oil reserve changes, 1999*

Pool	Initial established reserves (10 ³ m ³)		Main reason for change

[illegible]

2 Reserves of Crude Bitumen and Synthetic Crude Oil from Oil Sands

2.1 Provincial Summary

The EUB makes separate calculations of Alberta's crude bitumen reserves from oil sands by estimating those reserves likely to be recovered by mining methods and those by in situ methods. Previous reports indicated established reserves for in situ projects under active development only. This report, however, shows the EUB's estimate of the established reserves determined from those areas in which crude bitumen may reasonably be presumed to be recoverable by in situ methods. The EUB believes that this reporting change, which greatly increases the established in situ reserves, more realistically reflects the potential in Alberta for the recovery of crude bitumen.

The EUB estimates the initial volume in place of crude bitumen in Alberta as of December 31, 1999, to be 259.2 billion cubic metres (10^9 m^3). Remaining established reserves of crude bitumen by surface-mineable and in situ methods as of this date are estimated to be 27.85 billion cubic metres, of which 1.89 billion cubic metres are within active development areas. Table 2.1 gives a summary of the in-place and established mineable and in situ bitumen reserves.

Table 2.1. In-place volumes and established reserves of crude bitumen (10^9 m^3)

Recovery method	Initial volume in place	Initial established reserves	Cumulative production	Remaining established reserves	Remaining established reserves under active development
Mineable	18.0	5.59	0.35	5.24	1.39
In situ	241.2	22.74	0.13	22.61	0.50
Total	259.2 (1 631) ^a	28.33 (178.3) ^a	0.48 (3.0) ^a	27.85 (175.2) ^a	1.89 (11.9) ^a

^a Imperial equivalent in billions of stock-tank barrels.

The changes in established crude bitumen reserves for 1999 are shown in Table 2.2. The significant change shown for the in situ initial established reserves reflects the EUB's decision, introduced in the *Alberta's Reserves 1998* report, to not restrict estimates to areas under active development only. The portion of established crude bitumen reserves that are within approved surface-mineable and in situ areas under active development are shown in Tables 2.3 and 2.4 respectively.

Synthetic crude oil production resulting from the crude bitumen production from the current two surface mining projects amounted to 18.8 million cubic metres (10^6 m^3) in 1999, with 13.1 million cubic metres from the Syncrude project and 5.7 million cubic metres from the Suncor project.

2.2 Initial in-Place Volumes of Crude Bitumen

Alberta's massive crude bitumen resources are contained in sand and carbonate sedimentary formations in the Athabasca, Cold Lake, and Peace River oil sands areas. EUB-designated Oil Sands Areas (OSAs) define the areal extent of crude bitumen occurrence, and Oil Sands Deposits (OSDs) contain the specific geological zones declared as oil sands deposits.

Table 2.2. Change in established crude bitumen reserves (10⁶ m³)

	1999	1998	Change

^aImperial equivalent in millions of stock-tank barrels.

Initial in-place volumes of crude bitumen in each deposit were estimated using drillhole data and geophysical logs. The crude bitumen within the Cretaceous sands was determined using a minimum saturation cutoff of 3 mass per cent crude bitumen and a minimum saturated zone thickness of 1.5 m for in situ areas and 6 mass per cent and 3.0 m for surface-mineable areas. Previously, within the surface-mineable areas the values of 3 per cent and 1.5 m had been used. The crude bitumen within the carbonate deposits was determined using a minimum bitumen saturation of 30 per cent of pore volume and a porosity value of 5 per cent.

2.2.1 Surface Mineable Area

The Surface Mineable Area (SMA) is defined as that part of the Athabasca Wabiskaw-McMurray deposit where the total overburden and top reject generally do not exceed 75 m.

The initial volume in place and initial established mineable reserves have been recalculated to reflect the change in parameters mentioned above. The initial volume in place of crude bitumen within the potentially mineable areas is now estimated to be 18.0 billion cubic metres, down from 24.1 billion cubic metres. About 60 per cent of the reduction is a result of the higher bitumen cutoffs and the rest is a result of using revised modelling techniques.

2.2.2 In Situ Area

Calculation of the 1999 in situ resources includes a continuation of the conversion from the former manual process to an automated mapping and resource evaluation system. As a result, the resources for an increased number of the pools within the Cold Lake and Peace River areas have been determined from geological maps instead of by the original building-block method.

These volumetric resources are presented on a pool basis in the table "Crude Bitumen Resources and Basic Data" at the end of this section. Individual maps to year-end 1995 are provided in EUB *Statistical Series 96-38*.¹

The total initial volume of crude bitumen in place for the designated deposits as of December 31, 1999, was 241.2 billion cubic metres, down slightly from last year.

2.3 Surface-Mineable Crude Bitumen Reserves

Potential mineable areas were identified by updated (1999) economic strip ratio (ESR) criteria, a minimum saturation of 7 mass per cent bitumen, and a minimum saturated zone thickness of 3.0 m. The ESR criteria are fully explained in *ERCB Report 79-H*, Appendix III.² In previous reports values of 5 mass per cent and 1.5 m were used. This change more closely reflects the criteria used in operating mines.

The initial mineable volume in place of crude bitumen within the potentially mineable areas (those areas within the SMA that pass the above criteria) is estimated as of December 31, 1999, to be 9.4 billion cubic metres. The reduction in this estimate, from 11.2 billion cubic metres, is a result of the higher bitumen cutoffs, the updated ESR, and the use of revised modelling techniques.

Reduction factors were applied to this initial mineable resource volume to determine the established mineable reserve volume. These factors account for ore sterilization due to environmental protection corridors along major rivers (10 per cent), small isolated ore bodies (10 per cent), location of surface facilities (plant sites, tailings ponds, waste dumps) (10 per cent), and mining/extraction losses (18 per cent).

The resulting initial established mineable reserve of crude bitumen is estimated to be 5.6 billion cubic metres.

Only a small fraction of the initial established mineable reserve is under active development. Currently, Suncor and Syncrude are the only two producers in the SMA, and the cumulative bitumen production from these projects is 349 million cubic metres. Albian Sands Energy Inc. (a consortium of Shell, Chevron, and Western Oil Sands) has announced the start-up of the Muskeg River Mine; the reserves for this project are included in Table 2.3.

The remaining established mineable crude bitumen reserve as of December 31, 1999, is 5.2 billion cubic metres.

The crude bitumen reserves categories are presented in Figure 2.1.

Table 2.3 shows the remaining established mineable crude bitumen reserves from deposits under active development as of December 31, 1999.

2.4 Surface-Mineable Synthetic Crude Oil Reserves

The yield of synthetic crude oil through upgrading of crude bitumen depends upon the type of upgrading technology used, the use of products as fuel in the upgrading, the extent of gas liquids recovery, and the extent of residue upgrading. The overall liquid yield factor for the current Suncor delayed coking operation is 0.81, while that for the current fluid coking/hydrocracking operation at Syncrude is 0.85. The proposed overall liquid yield factor for the Albian Sands project, via the Shell upgrader using a hydrocracking process, is anticipated to be at or above 0.90.

The remaining established reserves of synthetic crude oil from the upgrading of the 5.2 billion cubic metres of crude bitumen in the SMA are estimated to be 4.6 billion cubic metres. This estimate is based on an average yield factor of 0.88, a slightly lower value than used previously, which reflects the different upgrading technologies presently being used and assumes improvements in coking operations that will increase liquid yield for future development of the SMA crude bitumen reserves.

2.5 In Situ Crude Bitumen Reserves

In previous reports, the EUB limited the determination of established in situ reserves to only those areas under active in situ development. Starting with this *Alberta's Reserves 1999* report, the EUB has determined an in situ initial established reserve for those areas considered amenable to in situ recovery methods. Reserves attributable to thermal development were determined using a minimum saturation cutoff of 3 mass per cent crude bitumen and a minimum zone thickness of 10.0 m. For primary development, the same saturation cutoff of 3 mass per cent was used with a minimum zone thickness of 3.0 m. Recovery factors of 20 per cent for thermal development and 5 per cent for primary development were applied to the areas within the cutoffs. These recovery factors are lower than some of the active project recovery factors to account for the uncertainty in the recovery processes and areal extent of the projects. The EUB's 1999 estimate of initial established reserves for in situ areas is 22.74 billion cubic metres. This reserve will be reviewed and refined in the future, as more information becomes available on the in place resource and the recovery processes used to extract the reserve.

Figure 2.1. Crude bitumen reserves categories

The EUB has assigned initial volumes in place and initial and remaining established reserves for commercial projects, primary recovery schemes, and active experimental schemes where all or a portion of the wells have been drilled and completed. An aggregate reserve is shown for all active experimental schemes, as well as an estimate of initial volumes in place and cumulative production. An aggregate reserve is also shown for all commercial and primary recovery schemes within a given oil sands deposit and area.

For commercial projects, only the areas actually developed for thermal recovery have been included in the established reserves, notwithstanding the size of the approved project areas. The initial volume in place for developed areas in each project is based on the assigned drainage areas and the volume in place has regard for the assigned spacing of the individual wells or well clusters. Established reserves were then determined for the currently approved recovery mechanism. Future experimentation and technological improvements may result in higher recovery of crude bitumen. For those projects with a primary recovery (pumping wells

at initial reservoir temperature) component, the in-place volume is based on the full development of all approved scheme areas.

The initial established primary reserves under primary development are based on a 5 per cent average recovery factor. The recovery factor of 25 per cent for thermal commercial projects reflects the application of various steaming strategies and project designs in the Cold Lake area.

The total initial established reserves of crude bitumen from active in situ areas is estimated to be 630.8 million cubic metres, an increase of 61.1 million cubic metres. The initial established reserves were determined by totalling the individual project reserves in each deposit. For the active experimental schemes, the initial established reserve figure of 1.7 million cubic metres is based on a composite recovery factor. The EUB's 1999 estimate of the established in situ crude bitumen reserves under active development is shown in Table 2.4.

2.6 Ultimate Potential of Crude Bitumen and Synthetic Crude Oil

The EUB estimates the ultimate volume of crude bitumen in place to be 400 billion cubic metres, consisting of about 24 billion cubic metres in deposits that may eventually be amenable to surface mining and the remainder being deeper deposits that will require the use of in situ recovery or underground mining techniques.

Although drilling and log analyses indicate the potential ultimate volume of crude bitumen in place to be some 400 billion cubic metres, knowledge of variations in quality and its effect on recovery potential is still limited. In addition, there has been little experimentation to date to establish the expected recovery factor for some types of resources, particularly carbonates. Therefore, the portions of in-place volumes for the Cretaceous sand and Paleozoic carbonate deposits that will require the use of in situ recovery methods were broken down into established and probable categories, and different recovery factors were applied to each category in establishing the ultimate potential of crude bitumen for the in situ areas. The recovery factors selected reflect the EUB's current knowledge respecting the quality of the in place reserves, the amount of experimentation done to date to establish recovery techniques, and a projection of future improvements in those techniques.

The ultimate potential of crude bitumen from Cretaceous sediments by in situ recovery methods is estimated to be some 33 billion cubic metres and from carbonate sediments some 6 billion cubic metres. About 10 billion cubic metres are expected from within the surface-mineable boundary and represent the initial mineable volume in place after accounting for losses in mining and extraction and quantities inaccessible in environmental buffer zone areas. For current projects, it is also assumed that tailings ponds and discard sites will either be located on nonmineable areas or will be removed from the mineable areas in order to recover underlying economic mineable ore. The total initial ultimate potential amount of crude bitumen recoverable is therefore about 49 billion cubic metres.

Table 2.4. Established in situ crude bitumen reserves in areas under active development as of December 31, 1999

Development	Initial volume in place ^a (10 ⁶ m ³)	Recovery factor (%)	Initial established reserves (10 ⁶ m ³)	Cumulative production ^b (10 ⁶ m ³)	Remaining established reserves (10 ⁶ m ³)

^aThermal reserves are assigned only for lands approved for thermal recovery and having completed drilling development.

^bCumulative production to December 31, 1999, includes amendments to production reports.

The yield of synthetic crude oil (including butanes and heavier liquid product) from crude bitumen will vary with the upgrading technology used. Also, it will depend upon the extent to which external energy sources, such as coal and natural gas, are used to satisfy fuel and feedstock requirements. The EUB considers that an average yield factor of 1.0 m³/m³ by volume can be achieved through the use of high-conversion hydrogen-addition upgrading technologies. However, in terms of ultimate synthetic crude oil reserves, hydrogen requirements would be extremely large, far exceeding estimated amounts that might be available by steam reforming of natural gas. Therefore, alternative sources of hydrogen, such as from partial oxidation using coal, coke, or pitch residuum, would have to be considered. Also, it is assumed that coal and natural gas may supply part of the fuel and feedstock needs. On these assumptions, the ultimate potential amount of synthetic crude oil recoverable is estimated at 49 billion cubic metres, with 10 billion cubic metres attributable to surface mining and 39 billion cubic metres to the in situ areas.

3 Reserves of Gas

3.1 Provincial Summary

The EUB estimates the remaining established reserves of marketable gas in Alberta at December 31, 1999, to be 1207 billion cubic metres (10^9 m^3), having a thermal (heating value) energy content of 46 exajoules. This represents a net decrease of 32.7 billion cubic metres since December 31, 1998, which is a result of all reserves additions less marketed production that occurred during 1999. The remaining established reserves includes about 39 billion cubic metres of ethane and NGL that would be extracted downstream at reprocessing plants and will be discussed in Volume 2 of this report.

Reserves additions for 1999 totalled 109.7 billion cubic metres, or 77 per cent of Alberta's production of 142.3 billion cubic metres. Reassessment accounted for 30.7 billion cubic metres, and drilling added the remaining 79 billion cubic metres. Drilling alone therefore replaced 56 per cent of Alberta's 1999 gas production.

The initial established reserves attributed to new pools booked in 1999 totalled 38.5 billion cubic metres, while development of existing pools added another 40.5 billion cubic metres. Figure 3.1 shows annual reserves changes since 1974.

Alberta's remaining established reserves of gas has been declining since 1983, as shown in Figure 3.2. Details of the changes in remaining reserves during 1999 are shown in Table 3.1.

Table 3.1 Reserves of marketable gas (10^9 m^3)

	(1 228.7) ^c		

^a May differ from actual production as reported in other statistical reports.

^b Imperial equivalent in billions of cubic feet at 14.65 pounds per square inch absolute and 60°F.

^c On basis of 37.4 MJ/m³ in 10^9 m^3 .

At year-end 1999 gas reserves were assigned to 26 270 pools in the province. Of these, 6349 pools have never been placed on production and had aggregate initial established reserves of marketable gas of 187.5 billion cubic metres.

3.2 Reserves of Gas Containing Hydrogen Sulphide

Some 26 per cent (309 billion cubic metres) of the province's remaining established reserves contain at least some hydrogen sulphide (H_2S) and are classed as "sour." About 32 per cent of gas marketed in 1999 was sour. The distribution of established reserves of sweet and sour gas is shown in Table 3.2.

Table 3.2. Distribution of sweet and sour gas reserves ($10^6 m^3$), 1999

Type of gas	Raw gas		Marketable gas		
	Initial volume in place	Initial producible	Initial established reserves	Net cumulative production	Remaining established reserves

3.3 Distribution of Gas Reserves

The distribution of reserves of marketable gas by pool size is shown in Table 3.4. For the purposes of this table, commingled pools are considered as one and the SE Alta Gas System (MU) is considered on a field basis.

Table 3.4. Distribution of gas reserves by pool size, 1999

Reserve range (10 ⁶ m ³)	Pools		Initial established marketable reserves		Remaining established marketable reserves	
	#	%	10 ⁶ m ³	%	10 ⁶ m ³	%
1500+	298	1.1	2 178	55.6	412	34.1

Total	26 270	100.0	3 919	100.0	1 207	100.0

Figure 3.3 shows gas pools discovered by size and year as of December 31, 1998. Table 3.8 and Figure 3.4 show the distribution of reserves by geological period and by formation. Table 3.6 lists those pools having the largest reserve changes over the past year.

Table 3.9 lists pools contained in each multifield pool, the individual initial established reserves assigned for each field, and the total initial established reserves for the multifield pool.

3.4 Unconnected Gas Reserve Review

Unconnected gas reserves are those assigned to pools that do not have any wells connected to a gathering system and/or have not been placed on production. The EUB and NEB planned and put into effect a staged process to review unconnected gas pools, as described in EUB *General Bulletin 95-16: Unconnected Gas Review 95-1*, dated October 13, 1995. Previous Statistical Series (ST) 18 reports, beginning with *ST 96-18*, documented the changes made to reserves as a result of the review of all unconnected pools discovered through 1988.

Unconnected Gas Review 99-1, a study of unconnected pools discovered in 1989 and reviewed in 1999, resulted in the deletion of 6.3 billion cubic metres of established reserves from the EUB/NEB database. As indicated in GB 99-14, the EUB and NEB did not analyze reserves from this study but relied on industry input regarding reserves retention.

The next study, *Unconnected Gas Review 2000-1*, will include all pools discovered in 1990, the eleventh year prior to the current year, and will be initiated in the summer of 2000. All future studies will continue to review the "eleventh" year from the current year on an ongoing basis.

3.5 Commercial Gas Storage Pools

Several pools in the province are being used for commercial gas storage to provide an efficient means of balancing supply with fluctuating market demand. Commercial gas storage is defined as the storage of third-party non-native gas and allows marketers to take

advantage of seasonal price differences, effect custody transfers, and maintain reliability of supply. Gas from many sources may be stored at these facilities under fee-for-service, buy-sell, or other contractual arrangements.

The remaining established marketable gas reserves for commercial gas storage pools can fluctuate depending on the supply and demand for gas. In the summer season when demand is lower, gas from other pools is injected into these pools. As the winter approaches, the demand for gas supply rises, injection slows or ends, and production generally begins at high withdrawal rates. Therefore, reserves for gas storage pools can vary significantly throughout this injection/production cycle and should only be considered reliable at the time of evaluation. Commercial gas storage pools, along with the operators and storage information, are listed in Table 3.5.

Table 3.5. Commercial gas storage pools as of December 31, 1999

Pool	Operator	Storage capacity (10⁶ m³)	Maximum deliverability (10³ m³/d)
Carbon Glauconitic	Canadian Western Natural Gas	1 125	17 000
Crossfield East Elkton A & D	Amoco Canada Petroleum Limited	1 114	11 000
McLeod Cardium A	Texaco Canada Petroleum Inc.	700	19 500
Suffield Upper Mannville I & K, and Bow Island N & BB	Alberta Energy Company Ltd.	2 395	50 710

3.6 Reserves of Pools Calculated on an Energy Basis

Reserves of major retrograde condensate pools are tabulated on both an energy and a volumetric basis. Table 3.7 lists the initial energy in place, the recovery factor and surface loss factor (both on an energy basis), and the initial marketable energy for each pool. The table also lists raw- and marketable-gas heating values used to convert from a volumetric to an energy basis. The volumetric reserves of these pools are included here in the Gas Reserves and Basic Data section, but with recovery factors and surface loss factors deleted.

3.7 Reserves of Ethane and Natural Gas Liquids Included in Gas Reserves

The remaining established reserves of natural gas discussed in Section 3.1 are determined at the field gate. A portion of the ethane and natural gas liquids (NGL) they contain enter trunk line systems and are extracted downstream at reprocessing plants. If the quantities to be extracted are deducted from the remaining established reserves of marketable gas, the gas reserves and the thermal energy content are reduced from 1207 billion cubic metres to 1168 billion cubic metres and from 46.0 to 42.8 exajoules respectively, as shown at the end of the Gas Reserves and Basic Data section.

Reserves of ethane and NGL are discussed in more detail in Volume 2 of this report.

3.8 Ultimate Potential

In 1992 the EUB (then the ERCB) issued *ERCB 92-A*,¹ which presented the results of its detailed review of Alberta's ultimate potential of marketable gas reserves. This review took into consideration geological prospects, technology, and economics. The EUB adopted an estimate of 5600 billion cubic metres as Alberta's ultimate potential for marketable gas. Figure 3.5 shows the historical and forecast growth in initial established reserves of marketable gas.

Figure 3.6 illustrates that 48 per cent of the estimated ultimate potential gas reserves has been produced to year-end 1999. Remaining established reserves of 1207 billion cubic metres account for 21 per cent of the ultimate potential. Initial established reserves therefore account for 69 per cent of the ultimate potential, leaving 31 per cent, or 1681 billion cubic metres, of natural gas reserves remaining to be discovered. This number added to the remaining established gas reserves yields 2888 billion cubic metres of natural gas, or 52 per cent of the ultimate potential, which will be available for future use.

In 1999 natural gas followed the trend of increasing production that has been seen in the last few years. This trend of increased production combined with a decline in remaining established reserves has resulted in a decline in the reserve-to-production ratio to the 1999 value of 8.5. The reserve-to-production ratio represents the remaining established reserves at year-end divided by the annual production (i.e., based on current production and no new drilling, the remaining established reserves would be produced in 8.5 years). With deregulation in 1986, the reserve-to-production ratio has been declining as gas production increased and remaining established reserves declined. Since there were abundant shut-in gas reserves, gas exploration lagged behind development of existing reserves, thus contributing to a decline in the ratio. As seen in Figure 3.6, there is considerable ultimate gas potential—1681 billion cubic metres—yet to be discovered, which will mitigate the impact of these declines. Therefore, this ratio in no way represents the number of producing years remaining. Additions to existing pools and the discovery of new pools will continue to bring on new reserves and associated production each year. The ratio within Alberta is expected to flatten similarly to that observed in basins within the United States. The United States deregulated its gas industry in 1978 and the reserve-to-production ratio has remained virtually unchanged between 8 and 12 for the last two decades.

3.9 Discussion of Reserves — Gas Reserves and Basic Data Section

The established reserves of gas are listed alphabetically by field or strike area in the Gas Reserves and Basic Data section. The data presented are condensed from the gas reserve system data file. Pools having initial marketable gas reserves equal to or greater than 300 million cubic metres (10^6 m^3) are listed individually. Pools having reserves less than 300 million cubic metres are grouped within each field or area and presented as a total. The total reserve in a field or area is given in the last entry.

¹Energy Resources Conservation Board, 1992, *Ultimate Potential and Supply of Natural Gas in Alberta* (Calgary).

Where production from two or more pools is commingled before measurement, the initial reserve estimate for each pool is shown, if available, together with the total reserve estimate for the pools. Similarly, because production of associated and solution gas reserves for a pool has not been determined separately, the Gas Reserves and Basic Data section shows remaining associated and solution gas reserves only on a combined basis.

Gas reserves in communication with crude bitumen are classified as nonassociated reserves in this report.

The amount of marketable gas produced from a pool is determined by adjusting the cumulative raw gas production from the pool for the estimated surface loss. Where gas has been injected for the enhanced recovery of oil, cycling of gas pools, and gas storage, the volumes of injected gas are included in the remaining established reserves of marketable gas (column 6) of the respective pools. The volumes credited to the pools have been adjusted to reflect projected losses in the reservoir and in handling and processing.

The marketed gas production generated by the gas reserves system for 1999 was 142.3 billion cubic metres. The actual net production of marketable gas, as determined from production reports, was 144.7 billion cubic metres. The difference is due to changes to errors or to amendments to previously reported cumulative raw gas production reports for some pools, as well as to adjustments made to the injected gas volumes discussed above. It is emphasized that as a result of this, net production volumes for any year should not be calculated from cumulative numbers appearing in this and previous reports.

The major purchasers of gas from particular fields are shown in column 20. This information has been updated to year-end 1999 based on the lands under contract data provided to the EUB by those purchasers.

Table 3.6. Major gas reserve changes (10^6 m^3), 1999

psia	pounds per square inch absolute
psig	pounds per square inch gauge
stb	stock-tank barrel

4.2 SI Units

Data in *Alberta's Reserves* are presented in the International System of Units (SI). The provincial totals and a few other major totals are shown in both SI units and the imperial equivalents in the various tables.

Conversion factors used in calculating the imperial equivalents are listed below:

1 m ³ of gas (101.325 kPa and 15°C)	= 35.493 73 cubic feet of gas (14.65 psia and 60°F)
1 m ³ of ethane (equilibrium pressure and 15°C)	= 6.33 Canadian barrels of ethane (equilibrium pressure and 60°F)
1 m ³ of propane (equilibrium pressure and 15°C)	= 6.300 0 Canadian barrels of propane (equilibrium pressure and 60°F)
1 m ³ of butanes (equilibrium pressure and 15°C)	= 6.296 8 Canadian barrels of butanes (equilibrium pressure and 60°F)
1 m ³ of oil or pentanes plus (equilibrium pressure and 15°C)	= 6.292 9 Canadian barrels of oil or pentanes plus (equilibrium pressure and 60°F)
1 m ³ of water pressure and 15°C)	= 6.290 1 Canadian barrels of water (equilibrium (equilibrium pressure and 60°F)
1 tonne	= 0.984 206 4 (U.K.) long tons (2240 pounds)
1 tonne	= 1.102 311 short tons (2000 pounds)
1 kilojoule	= 0.948 213 3 British thermal units (Btu as defined in the federal Gas Inspection Act (60°- 61°F))

4.3 Reserves Terminology

The reserves terminology used in this report applies to all fossil energy resources (including coal) and is as follows:

Initial Volume in Place: The volume of crude oil, crude bitumen, or raw natural gas calculated or interpreted to exist in a reservoir before any volume has been produced.

Established Reserves: Those reserves recoverable under current technology and present and anticipated economic conditions specifically proved by drilling, testing, or production, plus the portion of contiguous recoverable reserves that are interpreted to exist from geological, geophysical, or similar information with reasonable certainty.

Initial Established Reserves: Established reserves prior to the deduction of any production.

Remaining Established Reserves: Initial established reserves less cumulative production.

Ultimate Potential: An estimate of the initial established reserves that will have been developed in an area by the time all exploratory and development activity has ceased, having regard for the geological prospects of that area and anticipated technology and economic conditions.

Ultimate potential includes cumulative production, remaining established reserves, and future additions through extensions and revisions to existing pools and the discovery of new pools. Ultimate potential can be expressed by the following simple equation: Ultimate potential = initial established reserves + additions to existing pools + future discoveries.

The above terminology and definitions were recommended by the Inter-Provincial Advisory Committee on Energy and adopted by the EUB.

4.4 Other Terminology

Area	The area used to determine the bulk rock volume of the oil-, crude bitumen-, or gas-bearing reservoir, usually the area of the zero isopach or the assigned area of a pool or deposit.
Butanes	In addition to its normal scientific meaning, a mixture mainly of butanes that ordinarily may contain some propane or pentanes plus (Oil and Gas Conservation Act, Section 1(1)(c.1)).
Compressibility Factor	A correction factor for nonideal gas determined for gas from a pool at its initial reservoir pressure and temperature and, where necessary, including factors to correct for acid gases.
Condensate	A mixture mainly of pentanes and heavier hydrocarbons that may be contaminated with sulphur compounds and is recovered or is recoverable at a well from an underground reservoir. It may be gaseous in its virgin reservoir state but is liquid at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(d.1)).
Crude Bitumen	A naturally occurring viscous mixture mainly of hydrocarbons heavier than pentane that may contain sulphur compounds and that in its

naturally occurring viscous state will not flow to a well (Oil Sands Conservation Act, Section 1(1)(f)).

Crude Oil (Conventional)	A mixture mainly of pentanes and heavier hydrocarbons that may be contaminated with sulphur compounds and is recovered or is recoverable at a well from an underground reservoir. It is liquid at the conditions under which its volume is measured or estimated and includes all other hydrocarbon mixtures so recovered or recoverable except raw gas, condensate, or crude bitumen (Oil and Gas Conservation Act, Section 1(1)(f.1)).
Crude Oil (Heavy)	Crude oil is deemed to be heavy crude oil if it has a density of 900 kg/m^3 or greater, but the EUB may classify crude oil otherwise than in accordance with this criterion in a particular case, having regard to its market utilization and purchasers' classification.
Crude Oil (Light-Medium)	Crude oil is deemed to be light-medium crude oil if it has a density of less than 900 kg/m^3 , but the EUB may classify crude oil otherwise than in accordance with this criterion in a particular case, having regard to its market utilization and purchasers' classification.
Crude Oil (Synthetic)	A mixture mainly of pentanes and heavier hydrocarbons that may contain sulphur compounds and is derived from crude bitumen. It is liquid at the conditions under which its volume is measured or estimated and includes all other hydrocarbon mixtures so derived (Oil and Gas Conservation Act, Section 1(1)(t.1)).
Datum Depth	The approximate average depth relative to sea level of the midpoint of an oil or gas productive zone for the wells in a pool.
Density	The mass or amount of matter per unit volume.
Density, Relative (Raw Gas)	The density relative to air of raw gas upon discovery, determined by an analysis of a gas sample representative of a pool under atmospheric conditions.
Discovery Year	The year when drilling was completed of the well in which the oil or gas pool was discovered.
Ethane	In addition to its normal scientific meaning, a mixture mainly of ethane that ordinarily may contain some methane or propane (Oil and Gas Conservation Act, Section 1(1)(h.1)).
Gas	Raw gas, marketable gas, or any constituent of raw gas, condensate, crude bitumen, or crude oil that is recovered in processing and is gaseous at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(j.1)).

Gas (Associated)	Gas in a free state in communication in a reservoir with crude oil under initial reservoir conditions.
Gas (Marketable)	A mixture mainly of methane originating from raw gas, or if necessary from the processing of the raw gas for the removal or partial removal of some constituents, and that meets specifications for use as a domestic, commercial, or industrial fuel or as an industrial raw material (Oil and Gas Conservation Act, Section 1(1)(m)).
Gas (Marketable at 101.325 kPa and 15°C)	The equivalent volume of marketable gas at standard conditions.
Gas (Nonassociated)	Gas that is not in communication in a reservoir with an accumulation liquid hydrocarbons at initial reservoir conditions.
Gas (Raw)	A mixture containing methane, other paraffinic hydrocarbons, nitrogen, carbon dioxide, hydrogen sulphide, helium, and minor impurities, or some of these components, that is recovered or is recoverable at a well from an underground reservoir and is gaseous at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(s.1)).
Gas (Solution)	Gas that is dissolved in crude oil under reservoir conditions and evolves as a result of pressure and temperature changes.
Gas-Oil Ratio (Initial Solution)	The volume of gas (in cubic metres, measured under standard conditions) contained in one stock-tank cubic metre of oil under initial reservoir conditions.
Good Production Practice (GPP)	Production of crude oil or raw gas at a rate (i) not governed by a base allowable, but (ii) limited to what can be produced without adversely and significantly affecting conservation, the prevention of waste, or the opportunity of each owner in the pool to obtain its share of the production (Oil and Gas Conservation Regulation 1.020(2)9). This practice is authorized by the EUB either to improve the economics of production from a pool and thus defer its abandonment or to avoid unnecessary administrative expense associated with regulation or production restrictions where this serves little or no purpose.
Gross Heating (of Dry Gas)	The heat liberated by burning moisture-free gas at standard conditions and condensing the water vapour to a liquid state.
Mean Formation Depth	The approximate average depth below kelly bushing of the midpoint of an oil or gas productive zone for the wells in a pool.

Methane	In addition to its normal scientific meaning, a mixture mainly of methane that ordinarily may contain some ethane, nitrogen, helium, or carbon dioxide (Oil and Gas Conservation Act, Section 1(1)(m.1)).
Natural Gas Liquids	Propane, butanes, pentanes plus, or a combination of these obtained from the processing of raw gas or condensate (Oil and Gas Conservation Act, Section 1(1)(n)).
Oil	Condensate, crude oil, or a constituent of raw gas, condensate, or crude oil that is recovered in processing and is liquid at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(n.1)).
Oil Sands	(i) sands and other rock materials containing crude bitumen, (ii) the crude bitumen contained in those sands and other rock materials, and (iii) any other mineral substances other than natural gas in association with that crude bitumen or those sands and other rock materials referred to in subclauses (i) and (ii) (Oil Sands Conservation Act, Section 1(l)(o)).
Oil Sands Deposit	A natural reservoir containing or appearing to contain an accumulation of oil sands separated or appearing to be separated from any other such accumulation (Oil and Gas Conservation Act, Section 1(1)(o.1)).
Pay Thickness (Average)	The bulk rock volume of a reservoir of oil, oil sands, or gas divided by its area.
Pentanes Plus	A mixture mainly of pentanes and heavier hydrocarbons that ordinarily may contain some butanes and is obtained from the processing of raw gas, condensate, or crude oil (Oil and Gas Conservation Act, Section 1(1)(p)).
Pool	A natural underground reservoir containing or appearing to contain an accumulation of oil or gas or both separated or appearing to be separated from any other such accumulation (Oil and Gas Conservation Act, Section 1(1)(q)).
Porosity	The effective pore space of the rock volume determined from core analysis and well log data measured as a fraction of rock volume.
Pressure (Initial)	The reservoir pressure at the reference elevation of a pool upon discovery.
Propane	In addition to its normal scientific meaning, a mixture mainly of propane that ordinarily may contain some ethane or butanes (Oil and Gas Conservation Act, Section 1(1)(s)).
Recovery (Enhanced)	The increased recovery from a pool achieved by artificial means or by the application of energy extrinsic to the pool. The artificial means or application includes pressuring, cycling, pressure maintenance, or

injection to the pool of a substance or form of energy but does not include the injection in a well of a substance or form of energy for the sole purpose of

- (i) aiding in the lifting of fluids in the well, or
- (ii) stimulation of the reservoir at or near the well by mechanical, chemical, thermal or explosive means (Oil and Gas Conservation Act, Section 1(1)(h)).

Recovery (Pool)	In gas pools, the fraction of the in-place reserves of gas expected to be recovered under the subsisting recovery mechanism.
Recovery (Primary)	Recovery of oil by natural depletion processes only measured as a volume thus recovered or as a fraction of the in-place oil.
Saturation (Gas)	The fraction of pore space in the reservoir rock occupied by gas upon discovery.
Saturation (Water)	The fraction of pore space in the reservoir rock occupied by water upon discovery.
Shrinkage Factor (Initial)	The volume occupied by one cubic metre of oil from a pool measured at standard conditions after flash gas liberation consistent with the surface separation process and divided by the volume occupied by the same oil and gas at the pressure and temperature of a pool upon discovery.
Solvent	A suitable mixture of hydrocarbons ranging from methane to pentanes plus but consisting largely of methane, ethane, propane, and butanes for use in enhanced-recovery operations.
Surface Loss	A summation of the fractions of recoverable gas that is removed as acid gas and liquid hydrocarbons and is used as lease or plant fuel or is flared.
Temperature	The initial reservoir temperature upon discovery at the reference elevation of a pool.
Zone	Any stratum or sequence of strata that is designated by the EUB as a zone (Oil and Gas Conservation Act, Section 1(1)(z)).

4.5 Standard Conditions of Gas Measurement

Volumes of gas are given as at a standard pressure and temperature of 101.325 kPa and 15°C respectively.

Overview

What This Report Contains

This is Volume 2 of *Alberta's Reserves Report 1999*, which is updated and published annually by the Alberta Energy and Utilities Board (EUB). Volume 2 includes estimates of reserves for ethane, natural gas liquids, and sulphur. This edition reflects changes that have occurred to the end of 1999.

This is the first time that *Alberta's Reserves* (Statistical Series 18) has been separated into two volumes. Volume 1 was released in May 2000 and includes reserves of crude oil, oil sands, and natural gas.

The following table provides summary information on ethane, NGL, and sulphur reserves based on the EUB's estimate of established gas reserves. The increase in initial established reserves of ethane and NGL is the result of the increase in initial established gas reserves. Initial established reserves of sulphur increased due mainly to an increase in bitumen reserves under active development (see Volume 1 of this report for details).

Reserve Highlights 1999		
Reserves	1999	Change from 1998
Ethane		
Initial established (10^6 m ³)	739.0	+14.2
Cumulative net production	483.0	+26.2
Remaining established (10^6 m ³)	256.0	-12.0
NGL		
Initial established (10^6 m ³)	766.0	+4.0
Cumulative net production	552.3	+21.2
Remaining established (10^6 m ³)	213.7	-17.2
Sulphur		
Initial established (10^6 t)	309.0	+27.9
Cumulative production	199.8	+7.8
Remaining established (10^6 t)	109.2	+20.1

The EUB estimates yet-to-be-established gas reserves of 1681 billion cubic metres. This will yield reserves yet to be established for ethane and NGL of 291 and 394 million cubic metres respectively. Likewise, 128.7 million tonnes of sulphur are yet to be established from future gas discoveries, not to mention significant quantities of sulphur that will be recovered from the production of crude bitumen.

The Terminology section lists metric units and the imperial equivalents used in tables throughout the report, a glossary of specialized terminology, and symbols and abbreviations used in the report.

1 Reserves of Ethane

This section discusses the 1999 production of ethane and represents the EUB's estimate of the total volume of ethane contained in the remaining established reserves of gas. Although the EUB believes that ethane extraction at crude oil refineries and at plants processing synthetic crude oil might become viable in the future, it has not attempted to estimate the prospective reserves from those sources.

1.1 Provincial Summary

A computer file of compositional gas analyses and remaining established reserves was used in preparing the ethane reserve estimates in this section. Where a gas analysis was not available for a particular pool, a field or area average for the zone was used. The EUB estimates the remaining ethane volume from the total remaining established reserves of marketable gas to be 256 million cubic metres in liquefied form or 72.1 billion cubic metres in gaseous form. This estimate includes 28 million cubic metres recoverable from the ethane component of the solvent bank injected into several pools throughout the province to enhance oil recovery. Based on the EUB's estimated ultimate potential of 1030 million cubic metres, there remains 291 million cubic metres yet to be established. The overall changes in reserves during the past year are shown in Table 1.1.

Table 1.1 Ethane reserves (10^6 m^3) in liquefied form as of December 31, 1999

	1999	1998	Change
Initial established	739.0	724.8	+14.2
Cumulative net production	483.0	456.8	+26.2
Remaining established	256.0	268.0	-12.0

For individual gas pools, the ethane content of marketable gas in Alberta falls within the range of 0.0025 to 0.20 mole per mole. As shown in Table 1.2, the volume-weighted average ethane content of all remaining established marketable gas was 0.053 mole per mole. This table also gives a breakdown of ethane volumes recoverable from major fields, all other remaining fields, and solvent floods. Fields with liquid ethane reserves greater than 3 million cubic metres are classified as major fields and are listed in Table 1.3.

1.2 Ethane Extraction

The three principle sources of ethane extraction from natural gas are field plants with deep-cut facilities, fractionation plants, and straddle plants. Straddle plants extract the majority of ethane while the volume of extraction from fractionation plants is growing. Field plants with deep-cut facilities represent a small portion of the ethane recovered. Table 1.4 shows ethane extraction volumes at the three plant types in 1999.

Table 1.2. Remaining ethane reserves as of December 31, 1999

Fields	Remaining established reserves of marketable gas (10 ⁹ m ³)	Ethane content (mol/mol)	Volume of ethane	
			Gas (10 ⁹ m ³)	Liquid (10 ⁶ m ³)

In 1999 ethane extracted at gas processing facilities increased 9 per cent to 11.3 million cubic metres from 10.3 million cubic metres in 1998. The Dow Fort Saskatchewan plant saw a major increase in ethane recovery late in 1999.

Table 1.4 Ethane extraction volumes at the three plant types during 1999

Plants	Volume (10⁶ m³)
Straddle	6.4
Fractionation plants	4.0
Gas plants	<u>0.9</u>
Total	11.3

Presently some 80 per cent of extracted ethane is used by the petrochemical industry as feedstock to produce ethylene, while the remainder is exported out of the province. In 1999 some 43 per cent of ethane was extracted from natural gas, while the remainder was left in the gas stream and used for its heating value. As the industry continues to grow, the demand for ethane also increases. By applying present technology to ethane recovery processes, some 80 per cent of ethane contained in Alberta's gas production could be recovered.

2 Reserves of Natural Gas Liquids

Natural gas liquids (NGL) are defined in the Oil and Gas Conservation Act as "propane, butanes, or pentanes plus, or a combination of them, obtained from the processing of raw gas or condensate."

2.1 Provincial Summary

The EUB estimates the remaining established reserves of natural gas liquids in Alberta as of December 31, 1999, to be 213.7 million cubic metres. This represents a net decrease of 17.2 million cubic metres since December 31, 1998. Based on the EUB's estimated ultimate potential of 1 160 million cubic metres of natural gas liquids, there remains 394 million cubic metres yet to be established. The overall changes in the reserves during the past year are shown in Table 2.1. The fields with the largest changes for 1999 are shown in Table 2.2.

Table 2.1. Reserves of natural gas liquids (10^6 m^3) as of December 31, 1999

	1999	1998	Change
Initial established			
Propane	269.0	266.8	+2.2
Butanes	155.7	154.3	+1.4
Pentanes plus	<u>341.3</u>	<u>340.9</u>	<u>+0.4</u>
Total	766.0	762.0	+4.0
Cumulative net production ^a			
Propane	186.4	178.2	+8.2 ^b
Butanes	107.1	103.2	+3.9 ^b
Pentanes plus	<u>258.8</u>	<u>249.7</u>	<u>+9.1^b</u>
Total	552.3	531.1	+21.2
Remaining established			
Propane	82.6	88.6	-6.0
Butanes	48.6	51.1	-2.5
Pentanes plus	<u>82.5</u>	<u>91.2</u>	<u>-8.7</u>
Total	213.7	230.9	-17.2

^a Net production means production less those volumes returned to the formation or injected to enhance the recovery of oil.

^b Discrepancies may exist with actual production as reported in *Statistical Series 2000-17*.

Also during 1999, propane and butanes recovery at crude oil refineries was 354.15 and 899.2 thousand cubic metres respectively.

2.2 Determination of Recoverable Reserves of Natural Gas Liquids

The remaining established reserves of natural gas liquids consist of liquids that are expected to be extracted from the province's remaining established reserves of raw gas. The liquids recoverable from pools currently producing and connected to field gas processing plants were generally determined using remaining recoverable raw gas reserves, a raw gas analysis, and the current plant recovery efficiency for each component. For retrograde condensate pools where gas is cycled, product recoveries have been

Table 2.2. Major natural gas liquids reserves changes (10^3 m^3), 1999

Field	Remaining established 1999	Reserves change	Main reason for change
Brazeau River	5285	-1414	Reevaluation of reserves
Elmworth	2866	+724	Reevaluation of reserves
Gold Creek	620	-1123	Reevaluation of reserves
Karr	1776	-1868	Reevaluation of reserves
Wapiti	2367	+1419	Reevaluation of reserves

determined from individual reservoir studies, having regard for anticipated future cycling and blowdown operations. The remaining established reserves also include NGL estimated for unconnected reserves.

Table 2.3 shows the natural gas liquid reserves broken down into connected, unconnected, and solvent flood categories.

Table 2.3 Remaining established reserves (10^6 m^3) as of December 31, 1999

	Propane	Butanes	Pentanes plus	Total
Connected	68.2	39.6	70.5	178.3
Unconnected	14.1	7.7	11.4	33.2
Solvent floods	0.3	1.3	0.6	2.2
Total	82.6	48.6	82.5	213.7

Natural gas liquids are also recoverable at straddle plants. This volume is estimated by multiplying the remaining marketable gas reserves by the historic ratio of liquid production to marketable gas production. This assumes that the liquid content of marketable gas volume to be processed at straddle plants will remain constant. The EUB believes that the approach gives a reasonable indication of the natural gas liquids recoverable at these plants. The volumes recoverable at straddle plants are not included in the field totals and are shown separately in Table 2.4. Also listed in Table 2.4 are fields containing 800 000 cubic metres or more of recoverable reserves, while those with less are grouped under confidential and other small reserves categories. Note that some fields containing less than 800 000 cubic metres have been listed individually in this table for historical reasons.

2.3 Extraction of Propane, Butanes, and Pentanes Plus

Natural gas liquids are recovered from several sources, including gas processing plants in the field that extract propane, butanes, and pentanes plus as products or recover an NGL mix from raw gas production. NGL mixes are sent from gas processing plants to fractionation plants to recover individual NGL products. Straddle plants, usually at border points, also recover NGL products from marketable natural gas. A portion of the NGL mix from straddle plants is fractionated into individual products outside Alberta.

Propane is used in space heating, motor vehicles, barbecues, grain drying, and many other areas where an easily transportable fuel is required. The major use of butanes is as a feedstock in the production of methyl-tertiary-butyl-ether (MTBE), which when added to gasoline is an octane enhancer. Pentanes plus is a very light crude oil used as refinery feedstock for the production of gasoline and as a diluent to enable transportation of heavy crude oil and bitumen.

3 Reserves of Sulphur

3.1 Provincial Summary

The EUB estimates the remaining established reserves of elemental sulphur in the province as of December 31, 1999, to be some 109.2 million tonnes. The changes in sulphur reserves during the past year are as shown in Table 3.1.

Table 3.1. Reserves of sulphur (10⁶t) as of December 31, 1999

	1999	1998	Change
Initial established reserves

Total	109.2	89.1	+20.1

^aRecoverable reserves of elemental sulphur under active development at Suncor and Syncrude plants as of December 31, 1999.

3.2 Sulphur from Natural Gas

Sulphur stockpiles had accumulated at various gas plant sites in the province until 1978. When markets became available, these stockpiles were subsequently reduced from their peak in 1978 of 20.3 million tonnes to 2.4 million tonnes in 1991. Since then, sustained low prices for sulphur have caused the resumption of stockpiling. The sulphur stockpiled at year-end 1999 was 11.9 million tonnes, some 0.7 million tonnes greater than at year-end 1998.

The EUB recognizes 52.6 million tonnes of remaining established sulphur from conventional gas reserves at year-end 1999. This estimate from gas has been prepared by applying the appropriate hydrogen sulphide (H₂S) content and sulphur recovery efficiency to the remaining established reserves of raw gas in each pool. Where sulphur is currently being recovered, historical recovery efficiencies have been used. Where sulphur recovery is anticipated from gas reserves not yet being produced, the recovery efficiency has been estimated on the basis of the minimum sulphur recovery efficiency guidelines published in the EUB *Informational Letter (IL) 88-13*. The remaining established reserves of sulphur for cycling schemes were determined from a detailed assessment of each pool, but because the H₂S content in the gas changes with time, only the remaining sulphur reserves are

reported. The EUB estimates the ultimate potential for sulphur from conventional gas to be 330 million tonnes and from ultra-high H₂S pools to be 40 million tonnes. This leaves sulphur reserves of 128.7 million tonnes yet to be established from future discoveries of conventional gas.

The EUB's reserve estimates from natural gas are shown in Table 3.2. Fields containing 800 000 tonnes or more of recoverable sulphur are listed individually and those containing less are grouped under other small reserves. For historical reasons, some fields containing less than 800 000 tonnes of recoverable sulphur have also been included in this table. Sulphur reserves declined most notably in the Caroline, Crossfield East, and Gold Creek fields as a result of production.

3.3 Sulphur from Crude Bitumen

Crude bitumen in oil sands deposits contains significant amounts of sulphur. As a result of current upgrading operations in which bitumen is converted to synthetic crude oil, an average of 90 per cent of the sulphur contained in the crude bitumen is either recovered in the form of elemental sulphur or remains in products including coke.

It is currently estimated that some 211 million tonnes of elemental sulphur will be recoverable from the 5.2 billion cubic metres of remaining established crude bitumen reserves in the surface-mineable area. These sulphur reserves were estimated by multiplying the remaining established reserves of crude bitumen by a factor of 40.5 tonnes per thousand cubic metres of crude bitumen. In 1989, this ratio was revised from previous estimates to reflect both current operations and the expected use of high-conversion hydrogen-addition upgrading technologies for the future development of surface-mineable crude bitumen reserves. Hydrogen-addition technology yields a higher elemental sulphur production than does an alternative carbon-rejection technology, since a larger percentage of the sulphur in the bitumen remains in upgrading residues, as opposed to being converted to H₂S.

3.4 Sulphur from Crude Bitumen Reserves Under Active Development

Only a portion of the surface-mineable established crude bitumen reserves is under active development at the approved Suncor, Syncrude, and Shell projects. The EUB has estimated the initial established reserves from these projects to be 67.7 million tonnes, an increase of 25.1 million tonnes from 1998. This increase is due to expansion of the Suncor Steepbank/Millennium and Syncrude Aurora projects and the addition of the Shell Muskeg River project. Table 3.2 shows the amount of sulphur added for each project. A total of 11.1 million tonnes of elemental sulphur have been produced from these projects, leaving a remaining established reserve of 56.6 million tonnes. During 1999, 0.7 million tonnes of elemental sulphur were produced at the Suncor and Syncrude projects, the Shell project is still to come on stream.

Table 3.2 Addition of sulphur (10⁶ t) from crude bitumen under active development

Projects	Volume
Suncor Steepbank/Millennium	14.8
Syncrude Aurora	1.8
Shell Muskeg River	<u>8.5</u>
Total	25.1

^aVolume-weighted average.

^bAll recovery efficiencies are rounded to the nearest whole percentage.

^cIncludes gas-cycling pool. Gas reserves are calculated on an energy basis. H₂S content is not included because of gas composition changing with time.

4 Terminology

4.1 Symbols

SI

°C	degree Celsius
d	day
ha	hectare
J	joule
kg	kilogram
kPa	kilopascal

M	mega
m	metre
mol	mole
T	tera
t	tonne

Imperial

bbl	barrel
Btu	British thermal unit
cf	cubic foot
d	day

°F	degree Fahrenheit
psia	pounds per square inch absolute
psig	pounds per square inch gauge
stb	stock-tank barrel

4.2 SI Units

Data in *Alberta's Reserves* are presented using the International System of Units (SI). The provincial totals and a few other major totals are shown in both SI units and the imperial equivalents in the various tables.

Conversion factors used in calculating the imperial equivalents are listed below:

1 m ³ of gas (101.325 kPa and 15°C)	= 35.493 73 cubic feet of gas (14.65 psia and 60°F)
1 m ³ of ethane (equilibrium pressure and 15°C)	= 6.33 Canadian barrels of ethane (equilibrium pressure and 60°F)
1 m ³ of propane (equilibrium pressure and 15°C)	= 6.300 0 Canadian barrels of propane (equilibrium pressure and 60°F)
1 m ³ of butanes (equilibrium pressure and 15°C)	= 6.296 8 Canadian barrels of butanes (equilibrium pressure and 60°F)
1 m ³ of oil or pentanes plus (equilibrium pressure and 15°C)	= 6.292 9 Canadian barrels of oil or pentanes plus (equilibrium pressure and 60°F)
1 m ³ of water (equilibrium pressure and 15°C)	= 6.290 1 Canadian barrels of water (equilibrium pressure and 60°F)
1 tonne	= 0.984 206 4 (U.K.) long tons (2240 pounds)
1 tonne	= 1.102 311 short tons (2000 pounds)
1 kilojoule	= 0.948 213 3 British thermal units (Btu as defined in the federal Gas Inspection Act (60°-61°F))

4.3 Reserves Terminology

The reserves terminology used in this report applies to all fossil energy resources (including coal) and is as follows:

Initial Volume in Place: The volume of crude oil, crude bitumen, or raw natural gas calculated or interpreted to exist in a reservoir before any volume has been produced.

Established Reserves: Those reserves recoverable under current technology and present and anticipated economic conditions specifically proved by drilling, testing, or production, plus the portion of contiguous recoverable reserves that are interpreted to exist from geological, geophysical, or similar information with reasonable certainty.

Initial Established Reserves: Established reserves prior to the deduction of any production.

Remaining Established Reserves: Initial established reserves less cumulative production.

Ultimate Potential: An estimate of the initial established reserves that will have been developed in an area by the time all exploratory and development activity has ceased, having regard for the geological prospects of that area and anticipated technology and economic conditions.

Ultimate potential includes cumulative production, remaining established reserves, and future additions through extensions and revisions to existing pools and the discovery of new pools. Ultimate potential can be expressed by the following simple equation:
Ultimate potential = initial established reserves + additions to existing pools + future discoveries.

The above terminology and definitions were recommended by the Inter-Provincial Advisory Committee on Energy and adopted by the EUB.

4.4 Other Terminology

Area	The area used to determine the bulk rock volume of the oil-, crude bitumen-, or gas-bearing reservoir, usually the area of the zero isopach or the assigned area of a pool or deposit.
Butanes	In addition to its normal scientific meaning, a mixture mainly of butanes that ordinarily may contain some propane or pentanes plus (Oil and Gas Conservation Act, Section 1(1)(c.1)).
Compressibility Factor	A correction factor for nonideal gas determined for gas from a pool at its initial reservoir pressure and temperature and, where necessary, including factors to correct for acid gases.
Condensate	A mixture mainly of pentanes and heavier hydrocarbons that may be contaminated with sulphur compounds and is recovered or is recoverable at a well from an underground reservoir. It may be gaseous in its virgin reservoir state but is liquid at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(d.1)).

Crude Bitumen	A naturally occurring viscous mixture mainly of hydrocarbons heavier than pentane that may contain sulphur compounds and that in its naturally occurring viscous state will not flow to a well (Oil Sands Conservation Act, Section 1(1)(f)).
Crude Oil (Conventional)	A mixture mainly of pentanes and heavier hydrocarbons that may be contaminated with sulphur compounds and is recovered or is recoverable at a well from an underground reservoir. It is liquid at the conditions under which its volume is measured or estimated and includes all other hydrocarbon mixtures so recovered or recoverable except raw gas, condensate, or crude bitumen (Oil and Gas Conservation Act, Section 1(1)(f.1)).
Crude Oil (Heavy)	Crude oil is deemed to be heavy crude oil if it has a density of 900 kg/m ³ or greater, but the EUB may classify crude oil otherwise than in accordance with this criterion in a particular case, having regard to its market utilization and purchasers' classification.
Crude Oil (Light-Medium)	Crude oil is deemed to be light-medium crude oil if it has a density of less than 900 kg/m ³ , but the EUB may classify crude oil otherwise than in accordance with this criterion in a particular case, having regard to its market utilization and purchasers' classification.
Crude Oil (Synthetic)	A mixture mainly of pentanes and heavier hydrocarbons that may contain sulphur compounds and is derived from crude bitumen. It is liquid at the conditions under which its volume is measured or estimated and includes all other hydrocarbon mixtures so derived (Oil and Gas Conservation Act, Section 1(1)(t.1)).
Datum Depth	The approximate average depth relative to sea level of the midpoint of an oil or gas productive zone for the wells in a pool.
Density	The mass or amount of matter per unit volume.
Density, Relative (Raw Gas)	The density relative to air of raw gas upon discovery, determined by an analysis of a gas sample representative of a pool under atmospheric conditions.
Discovery Year	The year when drilling was completed of the well in which the oil or gas pool was discovered.
Ethane	In addition to its normal scientific meaning, a mixture mainly of ethane that ordinarily may contain some methane or propane (Oil and Gas Conservation Act, Section 1(1)(h.1)).
Feedstock	Raw material supplied to a refinery or petrochemical plant.
Field Plant	A plant located near the source of gas that processes raw gas and is located upstream of pipelines that move the gas to markets. Some of these plants extract ethane.

Fractionation Plant	A processing facility that takes an natural gas liquids stream and separates out the component parts as specification products.
Gas	Raw gas, marketable gas, or any constituent of raw gas, condensate, crude bitumen, or crude oil that is recovered in processing and is gaseous at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(j.1)).
Gas (Associated)	Gas in a free state in communication in a reservoir with crude oil under initial reservoir conditions.
Gas (Marketable)	A mixture mainly of methane originating from raw gas, or if necessary from the processing of the raw gas for the removal or partial removal of some constituents, and that meets specifications for use as a domestic, commercial, or industrial fuel or as an industrial raw material (Oil and Gas Conservation Act, Section 1(1)(m)).
Gas (Marketable at 101.325 kPa and 15°C)	The equivalent volume of marketable gas at standard conditions.
Gas (Nonassociated)	Gas that is not in communication in a reservoir with an accumulation liquid hydrocarbons at initial reservoir conditions.
Gas (Raw)	A mixture containing methane, other paraffinic hydrocarbons, nitrogen, carbon dioxide, hydrogen sulphide, helium, and minor impurities, or some of these components, that is recovered or is recoverable at a well from an underground reservoir and is gaseous at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(s.1)).
Gas (Solution)	Gas that is dissolved in crude oil under reservoir conditions and evolves as a result of pressure and temperature changes.
Gas-Oil Ratio (Initial Solution)	The volume of gas (in cubic metres, measured under standard conditions) contained in one stock-tank cubic metre of oil under initial reservoir conditions.
Good Production Practice (GPP)	Production of crude oil or raw gas at a rate (i) not governed by a base allowable, but (ii) limited to what can be produced without adversely and significantly affecting conservation, the prevention of waste, or the opportunity of each owner in the pool to obtain its share of the production (Oil and Gas Conservation Regulation 1.020(2)9). This practice is authorized by the EUB either to improve the economics of production from a pool and thus defer its abandonment or to avoid unnecessary administrative expense associated with regulation or production restrictions where this serves little or no purpose.

Gross Heating (of Dry Gas)	The heat liberated by burning moisture-free gas at standard conditions and condensing the water vapour to a liquid state.
Mean Formation Depth	The approximate average depth below kelly bushing of the midpoint of an oil or gas productive zone for the wells in a pool.
Methane	In addition to its normal scientific meaning, a mixture mainly of methane that ordinarily may contain some ethane, nitrogen, helium, or carbon dioxide (Oil and Gas Conservation Act, Section 1(1)(m.1)).
Natural Gas Liquids	Propane, butanes, pentanes plus, or a combination of these obtained from the processing of raw gas or condensate (Oil and Gas Conservation Act, Section 1(1)(n)).
Oil	Condensate, crude oil, or a constituent of raw gas, condensate, or crude oil that is recovered in processing and is liquid at the conditions under which its volume is measured or estimated (Oil and Gas Conservation Act, Section 1(1)(n.1)).
Oil Sands	(i) sands and other rock materials containing crude bitumen, (ii) the crude bitumen contained in those sands and other rock materials, and (iii) any other mineral substances other than natural gas in association with that crude bitumen or those sands and other rock materials referred to in subclauses (i) and (ii) (Oil Sands Conservation Act, Section 1(1)(o)).
Oil Sands Deposit	A natural reservoir containing or appearing to contain an accumulation of oil sands separated or appearing to be separated from any other such accumulation (Oil and Gas Conservation Act, Section 1(1)(o.1)).
Pay Thickness (Average)	The bulk rock volume of a reservoir of oil, oil sands, or gas divided by its area.
Pentanes Plus	A mixture mainly of pentanes and heavier hydrocarbons that ordinarily may contain some butanes and is obtained from the processing of raw gas, condensate, or crude oil (Oil and Gas Conservation Act, Section 1(1)(p)).
Pool	A natural underground reservoir containing or appearing to contain an accumulation of oil or gas or both separated or appearing to be separated from any other such accumulation (Oil and Gas Conservation Act, Section 1(1)(q)).
Porosity	The effective pore space of the rock volume determined from core analysis and well log data measured as a fraction of rock volume.
Pressure (Initial)	The reservoir pressure at the reference elevation of a pool upon discovery.

Propane	In addition to its normal scientific meaning, a mixture mainly of propane that ordinarily may contain some ethane or butanes (Oil and Gas Conservation Act, Section 1(1)(s)).
Recovery (Enhanced)	The increased recovery from a pool achieved by artificial means or by the application of energy extrinsic to the pool. The artificial means or application includes pressuring, cycling, pressure maintenance, or injection to the pool of a substance or form of energy but does not include the injection in a well of a substance or form of energy for the sole purpose of (i) aiding in the lifting of fluids in the well, or (ii) stimulation of the reservoir at or near the well by mechanical, chemical, thermal or explosive means (Oil and Gas Conservation Act, Section 1(1)(h)).
Recovery (Pool)	In gas pools, the fraction of the in-place reserves of gas expected to be recovered under the subsisting recovery mechanism.
Recovery (Primary)	Recovery of oil by natural depletion processes only measured as a volume thus recovered or as a fraction of the in-place oil.
Saturation (Gas)	The fraction of pore space in the reservoir rock occupied by gas upon discovery.
Saturation (Water)	The fraction of pore space in the reservoir rock occupied by water upon discovery.
Shrinkage Factor (Initial)	The volume occupied by one cubic metre of oil from a pool measured at standard conditions after flash gas liberation consistent with the surface separation process and divided by the volume occupied by the same oil and gas at the pressure and temperature of a pool upon discovery.
Solvent	A suitable mixture of hydrocarbons ranging from methane to pentanes plus but consisting largely of methane, ethane, propane, and butanes for use in enhanced-recovery operations.
Straddle Plant	A gas processing plant located on a main gas transmission pipeline that extracts natural gas liquids.
Surface Loss	A summation of the fractions of recoverable gas that is removed as acid gas and liquid hydrocarbons and is used as lease or plant fuel or is flared.
Temperature	The initial reservoir temperature upon discovery at the reference elevation of a pool.
Zone	Any stratum or sequence of strata that is designated by the EUB as a zone (Oil and Gas Conservation Act, Section 1(1)(z)).

4.5 Standard Conditions of Gas Measurement

Volumes of gas are given as at a standard pressure and temperature of 101.325 kPa and 15°C respectively.

4.6 Abbreviations

General Report

GIP	gas in place
GPP	good production practice
RF	recovery factor
RGE	range
STP	standard temperature and pressure
TWP	township
WM	west of a certain meridian
